

Models in Other Scientific Fields

- Astrophysics

- Computing the universe. . . numerical models of galaxies, accretion disks, extra-solar planets etc.

- Theoretical physics

- Use models make quantitative predictions and understand the phenomenology of string theory, etc. The Standard Model (or is that a theory?). The Ising model in condensed matter.

- Economics

- Numerical models in game theory, and how the macro-economy works, or doesn't.

- Ecology and Evolution

- Trying to make quantitative predictions in evolution, speciation, etc. Evolutionary dynamics.

- Making nuclear bombs

- Avoids the need for actual testing?

Climate seems to have the most developed models, in comparison with extant theory.

Evolution has an underlying theory (Darwinian theory et seq.), as well as various models of particular situations. Is there an underlying theory of climate?
